Exploring urine lab data patterns in renal failure during sepsis

INTRODUCTION:
There are no conclusive studies of the value of urinary biochemical patterns to predict outcome and RRT necessity (because of paucity of data) in the initial phase of sepsis

OBJECTIVE:
This project aims to review if conventional urine lab data in patients with sepsis predict which ones will develop AKI.

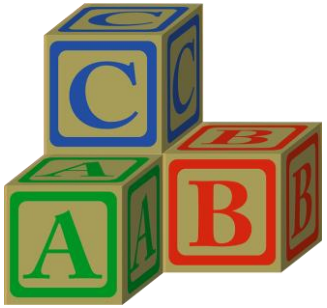
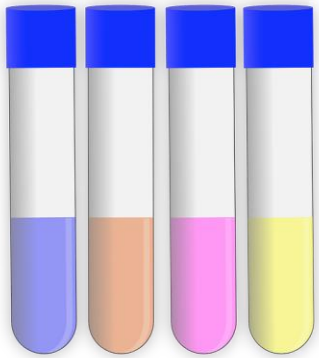
Conclusions



It is feasible to make a good model to predict AKI development (AUC 0,78).



We should take into account evaluate urinary urea nitrogen and lactate dehydrogenase
